Python Basics

A short test document for RAGdocAI

What is Python?

Python is a high-level, interpreted programming language. It is known for readable syntax and a large collection of libraries. Python is used in web development, automation, data analysis, artificial intelligence, and scientific computing.

Variables and Data Types

A variable stores a value. Common Python data types include integers, floating-point numbers, strings, and Boolean values. For example, age = 20 stores an integer, while name = 'Aisha' stores a string.

Functions

A function is a reusable block of code. Functions are defined with the def keyword. A function can accept parameters and return a result. Functions help organize programs into smaller, understandable parts.

Lists and Dictionaries

A list is an ordered, mutable collection. A dictionary stores key-value pairs. Lists are useful when items are accessed by position, while dictionaries are useful when values are accessed through meaningful keys.

Prepared as sample content for local RAGdocAI testing.
